KNOW-HOW

Low smoke density can mean the difference between life and death
FIRE FATALITIES ARE SMOKE FATALITIES

When fire breaks out, people usually only have 3 minutes to escape. Smoke spreads extremely rapidly, blocking escape and rescue routes. So technical insulation materials with low smoke development make a significant contribution to people’s safety in buildings.

On average, 11 people die in fires in the European Union every day. That means around 4,000 deaths a year among the 505 million inhabitants of the 28 EU countries. Over half of fires occur in buildings or vehicles and 90% of the fatalities are a result of these fires.

But only a few are killed by the flames, the majority – 95% of fire victims! – die as a result of smoke inhalation. When fire breaks out it is crucial that fire-fighters and those trapped find escape routes quickly and that is only possible with minimal smoke development.

Fires have disastrous consequences for industry, too: according to insurers, every third fire leads to damage to property amounting to more than 500,000 euros. All in all, fires cause 126 billion euros of property damage in Europe every year. Here too, smoke gases cause more damage than the flames. The secondary damage as a result of soot and corrosive gases accounts for over 50% of the total costs in a major fire.

Not to mention the follow-up costs due to production downtime. Avoiding damage due to soot and smoke on plant and equipment is not usually a declared protection objective in industrial buildings.

Low fire load through technical insulation
To limit the speed at which the fire spreads, the use of combustible construction products in buildings is usually restricted. But it is not possible to do without plastics, such as cables or synthetic insulation materials, completely. However, the contribution of combustible construction materials is often overestimated in relation to the building contents (e.g., the interior fittings) and only make up a very small fraction of the fire-load.

Because of their low density, plastics usually only contain 2 to 3 volume percent of combustible material and therefore only constitute a minor fire-load in comparison to compact materials [1].

Assessing the fire behaviour
The outbreak of the fire is the crucial phase for assessing the fire behaviour of synthetic insulation materials. The characteristic parameters for the fire behaviour of construction products are:

- Ignitability
- Flame spread
- Heat release (or temperature rise)
- Smoke development
- Burning droplets / particles

More realistic evaluation of the fire behaviour in the SBI test
Whereas in the national testing procedures for construction products technical insulation materials were primarily assessed according to their flame resistance, the classification criteria of the European SBI test (single burning item test) are much more complex and allow a more realistic assessment of the fire behaviour.

Armaflex Ultima is the first technical insulation material with extremely low smoke development. In comparison to a standard elastomeric product, Armaflex Ultima exhibits 10 times less smoke.
In order to distinguish the Euroclasses for linear products (such as insulation tubes) from flat products (insulation sheets), the former are marked with a subscripted L (short for linear).

In the SBI test smoke development and burning droplets are also measured. For this purpose additional classes have been developed which are marked with s (for smoke) and d (for droplets) [see Table 2].

Euroclass E is tested in accordance with EN ISO 11 925-2 [3] in the ignitability test. For classes A2 to D additional classification using the SBI test procedure in accordance with EN 13823 [4] is required.

The ignitability test assesses the ignitability of a construction product by exposing it to a small flame. The SBI test assesses the potential contribution of a construction product to a developing fire in a fire scenario which simulates a single burning item in a room corner close to this construction product (see Figure 2).

The test reproduces a realistic fire scenario, which can occur due to a burning waste-paper basket in a corner of the room, for example.

For flat products the values in Table 3. The limit values for flat products are considerably lower than the classification values for linear products, i.e. more difficult to achieve.

Conflict of objectives: combustibility vs. smoke development

Like all organic products flexible elastomeric insulation materials (FEFs) are combustible. In order to ensure that the insulation material is optimally protected against fire, various flame retardants are added [5]. Flame retardants are additives which reduce the ignitability and burning rate through physical and/or chemical action, but do not prevent the materials themselves being combustible. Up to now, organic-based technical insulation materials could only achieve the best construction materials classification for combustible building products with the aid of halogenated systems. While other flame retardants are only effective at relatively low temperatures, halogenated systems act directly on the combustion process at temperatures between 600 and 800 °C. Typical components of flame retardants are chlorine and bromine. Brominated flame retardants inhibit combustion very effectively, but due to their mode of action and their effect, they lead to high smoke development, especially in the gas phase. For this reason, standard elastomeric products achieve a good fire classification in the European SBI test – the majority of premium products are classified as ‘B’, i.e. of low flammability – but they tend to have high smoke development and so are mainly classified as ‘s3’. Elastomeric insulation materials with lower smoke development (‘s2’ or even ‘s1’), on the other hand, previously only achieved fire class E or at best D.

Elastomeric insulation materials with low smoke development

The insulation manufacturer Armacell has been able to resolve this conflict of objectives: due to the...
development of completely new, intrinsically flame-resistant polymers and using ablative protective additives it is no longer necessary to add any brominated flame retardant. The Armaflex Ultima foam combines for the first time extremely high flame resistance with minimal smoke development. The blue elastomeric foam is the first flexible insulation material to achieve fire class B₁-s₁,d₀. The product was developed on the basis of the innovative Armashield® technology, which is patented both in the USA (US patent no. 8,163,811) and in Europe (European patent no. 2 261 305). As Figure 3 shows, Armaflex Ultima develops 10 times less smoke than a standard elastomeric product.

**New safety standard in technical insulation**

With Armaflex Ultima Armacell has set a new safety standard in technical insulation. Based on the patented Armashield technology, the new foam is the first flexible technical insulation material in the world with fire class B₁-s₁,d₀, thus providing unsurpassed safety in a fire. Following the launch in 2012, the market leader further improved its recipe and added further products to complete the range. For insulating pipes with large outer diameters (> 89 mm ≤ 300 mm) Armacell provides “open tubes” – non-covered, slit tubes which achieve fire class B₁-s₁,d₀. News additions to the range are tubes and sheets in an insulation thickness of 32 mm. Apart from standard and self-adhesive tubes and sheets, Armacell provides an Ultima version of the tried-and-tested Armafix pipe support. The system solution for hanging pipes in cold applications is now manufactured with a load-bearing segment made of recycled PET.

Good fire behaviour is, however, just one of the key requirements for technical insulation materials. The products must also have low thermal conductivity and high resistance to water-vapour transmission. They should be closed cell and easy to install reliably even under difficult conditions on the building site.

**Safety first! Fire protection is the top priority**

Many European countries have already tightened the requirements regarding the smoke development of construction products in their building regulations. In Sweden, for example, only technical insulation materials that achieve at least fire class B₁-s₁,d₀ may be used in so-called Br1 buildings – these are buildings requiring special fire protection such as hotels or hospitals. With its Armaflex Ultima range, Armacell is the first manufacturer to offer a flexible, closed-cell product with fire classification B₁-s₁,d₀ to fulfil these requirements. Whether it is a case of building new or renovating existing residential and office buildings, schools, hospitals, hotels or industrial and commercial buildings, preventive fire protection must be the highest priority. Although it is never possible to completely rule out a fire occurring, the consequences of a blaze can be significantly reduced.
